BOX PATENT APPLICATION
Assistant Commissioner for Patents
Washington, D.C. 20231

Re: Application of **Norbert VENET, Claude DREVON, and Stephane ALBINET**

**MODULE INCLUDING AN INDUCTIVE WINDING AND METHOD OF
OBTAINING IT**
Our Ref. Q60260

Dear Sir:

Attached hereto is the application identified above including 9 sheets of the specification, claims and abstract, 1 sheet of formal drawings, executed Assignment and PTO 1595 form, and executed Declaration and Power of Attorney. Also enclosed is the Information Disclosure Statement.

The Government filing fee is calculated as follows:

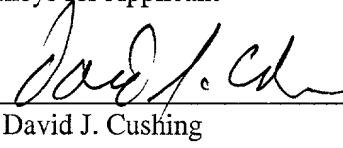

Total claims	<u>7</u>	-	<u>20</u>	=	<u>0</u>	x	\$18.00	=	<u>\$0.00</u>
Independent claims	<u>3</u>	-	<u>3</u>	=	<u>0</u>	x	\$78.00	=	<u>\$0.00</u>
Base Fee									\$690.00

TOTAL FILING FEE	<u>\$690.00</u>
Recordation of Assignment	<u>\$40.00</u>
TOTAL FEE	<u>\$730.00</u>

Checks for the statutory filing fee of \$690.00 and Assignment recordation fee of \$40.00 are attached. You are also directed and authorized to charge or credit any difference or overpayment to Deposit Account No. 19-4880. The Commissioner is hereby authorized to charge any fees under 37 C.F.R. §§ 1.16 and 1.17 and any petitions for extension of time under 37 C.F.R. § 1.136 which may be required during the entire pendency of the application to Deposit Account No. 19-4880. A duplicate copy of this transmittal letter is attached.

Priority is claimed from July 29, 1999 based on French Application No. 9909860. The priority document is enclosed herewith.

Respectfully submitted,
**SUGHRUE, MION, ZINN,
MACPEAK & SEAS, PLLC**

MODULE INCLUDING AN INDUCTIVE WINDING AND METHOD
OF OBTAINING IT

BACKGROUND OF THE INVENTION

Field of the invention

5 The invention relates to a method of obtaining a one-piece module including an inductive winding. It also relates to one-piece electronic modules, and in particular to modules with a winding around a magnetic core, obtained by means of the method, for example converter modules.

Description of the prior art

10 Producing windings consisting of superposed turns consisting of conductive tracks carried by a printed circuit folded on itself to align the turns along an axis corresponding to the axis of the winding to be obtained is known in the art.

The document US-A-5801611 describes an inductive device obtained in this way using a printed circuit on which winding turns are made on both faces at 15 locations of the circuit which are stacked in parallel planes by multiple folding of the circuit on itself. It is necessary to provide connections passing through the printed circuit to connect the interior end of the spiral assembly made up of turns at a location on the printed circuit to a corresponding end of the spiral assembly according to the winding to be obtained. These connections are conventionally 20 provided in the form of metal-plated holes which pass through the printed circuit to connect each of the two spiral assemblies. Solutions of this kind are relatively costly and relatively difficult to implement and their reliability is not always satisfactory.

SUMMARY OF THE INVENTION

The invention therefore proposes a method of obtaining a module including 25 at least one inductive winding made up of one or more conductive tracks on a printed circuit film support on which the tracks form turns which are combined to form a winding or a plurality of parallel and/or coaxial windings, which method includes the following steps:

- stacking a plurality of aligned modular printed circuit film elements carrying a set of turns which are intended to form part of a winding or of a plurality of parallel and/or coaxial windings and whose tracks terminate at or near the edge or one edge of the element that includes them,
- molding an insulative material over the stacked assembly of modular elements to constitute a rigid block,
- cutting the molded block laterally along the stack to expose the conductive

tracks at a common alignment level and so that they are flush with the surface of one face of the block, which cutting step is performed at least once, and

- creating connections on the face or faces of the block with which the modular conductive track elements are flush to interconnect them selectively and to connect them to connection means external to the module.

According to the invention, at least one end of a stack of modular elements is associated with one or more supplementary modular printed circuit elements which carry components and which have conductive tracks which terminate at a level corresponding to an alignment level of modular elements of the stack in order to perform the molding, cutting and connection creation steps simultaneously on all the associated modular elements.

In the context of the method according to the invention, an association of this kind enables a complete functional electronic module to be constructed by stacking modular elements and interconnecting all the modular elements by a connection operation common to all the elements.

According to the invention, at least one orifice is formed in the same position in the modular elements adapted to constitute a module to form therein a conduit enabling a core to be inserted through the modular elements.

This enables converter blocks including windings aligned along magnetic cores to be made in a minimum number of operations.

The invention also provides an electronic module in the form of a block which includes at least one inductive winding consisting of one or more conductive tracks on a printed circuit film support on which the tracks form turns which are combined to form the coil or parallel and/or coaxial coils, which module includes a stack of modular printed circuit film elements aligned at one edge at least and each carrying one or more turns which are to form part of a winding or of a plurality of parallel and/or coaxial windings and whose tracks terminate on a particular face at aligned edges of stacked modular elements at which conductive tracks are formed to connect turns to each other.

The resulting module has the advantage that it constitutes a rigid block, for example a cubical or rectangular parallelepipedal block, incorporating a connection network on at least one face.

In one variant of the invention the module is an electronic module incorporating a core and taking the form of a block which includes at least one winding made up of conductive tracks on a printed circuit film support adapted to

form turns, in a particular arrangement, and wherein at least some turns are combined to form a winding, which module includes a stack of modular printed circuit film elements aligned at one edge at least and each carrying one or more turns which are to form part of a winding or a plurality of parallel and/or coaxial

5 windings and whose tracks terminate at a face defined by aligned edges of stacked
modular elements on which are formed conductive connecting tracks for connecting
the turns to each other and to connection elements of external connection means,
and at least some of the adjacent modules in the stack include identical openings at
the center of at least one turn relating to a particular winding to form a passage for a
10 core housed in a conduit formed by successive modules incorporating such openings.

In one variant of the invention, the module is a converter module, for example, and at least one supplementary modular printed circuit element carrying components is embedded in the molded block at one end at least of the stack of elements forming a winding or windings and each supplementary element includes conductive tracks terminating at and electrically connected to conductive tracks formed on a particular face of the block by aligned edges of stacked modular elements.

The invention, its features and its advantages are explained in the following description, which is given with reference to the accompany drawing.

20 BRIEF DESCRIPTION OF THE DRAWING

The single figure of the accompanying drawing shows an electronic module according to the invention in section. The module includes an inductive winding constructed from conductive tracks forming turns around a magnetic core.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

25 The method according to the invention is for obtaining modules including one or more windings each made up of a plurality of turns in which the conductive member is a conductive track carried by a thin printed circuit, for example a printed circuit formed on a film.

The electronic module 1 shown by way of example in figure 1 includes an inductive winding around a magnetic core comprising two parts 2A, 2B abutted end-to-end. An arrangement of this kind is intended to constitute a converter, for example.

The module includes one or more windings around the middle tubular part of the core constituted by the two parts 2A and 2B abutted end-to-end. The windings 35 preferably have parallel and/or coaxial axes according to whether they have parallel

longitudinal axes or a common axis, in which case they can be concentric or aligned with each other, as required. In the remainder of the description, for simplicity, only one winding is referred to and is assumed to be aligned with the longitudinal axis YY' of the module.

5 The turns of the winding of the module consist of conductive tracks carried by a printed circuit film, in a manner known in the art, and define stacked repetitive spiral patterns. The stacking is along the longitudinal axis YY' in the module shown. According to the invention, the repetitive patterns are formed on separate modular printed circuit film elements which are intended to be stacked, as shown in the figure 10 for the film elements 3A. In this example, the film elements, such as the elements 3A and 3N, are rectangular in shape and incorporate an opening through which the middle tubular part of the core consisting of the two parts 2A, 2B abutted end-to-end passes. The turns carried by the film elements are formed identically around the central opening of the element that carries them. The conductive tracks which constitute them 15 extend as far as the periphery of the film element that carries them. In a preferred embodiment of the invention the film elements carrying turns which are intended to form part of the same stack preferably have the same dimensions and the conductive tracks forming their turns are reproduced identically on all the film elements.

20 The film elements which are intended to be stacked are aligned in a jig, for example by means of fixed rods included in the jig over which the film elements are placed, the film elements being provided with appropriate perforations at predetermined locations. The conductive tracks corresponding to the turns can extend to an alignment edge, for example, or can stop at the same distance from that edge. It is equally feasible to align different conductive tracks at different edges, in 25 particular at opposite edges of the elements, if necessary.

20 In a preferred embodiment of the method according to the invention of obtaining modules, the modular elements, such as the elements 3A, 3N, which are intended to be stacked to constitute a winding are stacked in a jig in which they are superposed exactly one on the other because of their identical dimensions and 30 because they are guided into position by the jig. The corresponding conductive track ends are then aligned, as symbolized by the straight line segment 5C and 5D in the figure. The aligned ends form rows parallel to the stacking axis, which in practice corresponds to the longitudinal axis YY' of the module obtained.

35 The resulting stack is then embedded in an insulative material, usually a polymer resin, which is hardened to form a block which in this example has regular

dimensions. The block is a rectangular parallelepiped, for example. In the case of a module including a magnetic core, the molding process leaves a passage 6 for the core through the modular film elements of the stack.

Supplementary modular printed circuit elements, such as the elements 7A, 7B, 7C, can be associated with at least one end of the stack in order to complete, from the functional point of view, the module which includes the winding obtained by stacking and to include the whole in the same molded block of insulative material. The supplementary printed circuit modular elements can be single-sided, double-sided or multilayer elements. They are used to mount components, for example 10 surface-mount components (SMC). The components can be positioned either on the outside of the block, such as the components 8A, 8B, or inside the block, such as the components 8C, 8D. Like the stacked modular elements 3A, 3N, the supplementary modular elements have conductive tracks which extend to an alignment edge of the element or end at the same distance from that edge.

15 The molding operation then takes place with the assembled modular elements, such as the elements 3A, 3N, 7A, 7B, 7C, disposed in the jig so that the modules are perpendicular to an axis corresponding to the longitudinal axis YY' of the module, along which the modules are pre-positioned, for example using a system of removable shims.

20 After molding, the resulting block is cut in a direction parallel to the longitudinal axis of the module so that the conductive tracks of the modular elements are flush with at least one lateral face of the molded block of the resulting module, such as the face 9.

25 Connections are then formed on the face or faces of the block with which the conductive tracks of the modular elements are flush in order to connect the latter to interconnection tracks and/or to connection members of connection means external to the module. In a preferred embodiment of the invention this operation is performed by metallizing at least the face or faces of the block concerned. Selective interconnection conductive tracks between modular elements, such as the elements 30 5C and 5D, and connection elements for connection means external to the module are thus formed on the metallized face or faces. For example, this is obtained by localized metallization or by metallization followed by selective elimination of the metal deposit sparing in particular the tracks and the areas provided for the connection elements where the conductive tracks of the modular printed circuit 35 elements are flush with the face or faces of the block concerned. The connection

elements are of the type conventionally provided for external connection means using balls or conductive tracks, for example of the lead frame type.

The conductive tracks on the faces of the block can be protected by depositing one or more layers of insulative material if required, as is standard

5 practice in the art.

In one particular embodiment, if the core housing 6 provided in the block opens to the exterior of the block, the module is completed by inserting the core. In the example shown, the two parts 2A, 2B of the core are therefore inserted from opposite sides of the module where their respective tubular parts join and are fixed together, for example glued together.

10 together, for example glued together.

THERE IS CLAIMED:

1. A method of obtaining a module including at least one inductive winding made up of one or more conductive tracks on a printed circuit film support on which said tracks form turns which are combined to form a winding or a plurality of parallel and/or coaxial windings, which method includes the following steps:

 - stacking a plurality of aligned modular printed circuit film elements carrying a set of turns which are intended to form part of a winding or of a plurality of parallel and/or coaxial windings and whose tracks terminate at or near the edge or one edge of the element that includes them,
 - molding an insulative material over the stacked assembly of modular elements to constitute a rigid block,
 - cutting the molded block laterally along the stack to expose the conductive tracks at a common alignment level and so that they are flush with the surface of one face of the block, which cutting step is performed at least once, and
 - creating connections on the face or faces of the block with which the modular conductive track elements are flush to interconnect them selectively and to connect them to connection means external to the module.
2. The method claimed in claim 1 wherein at least one end of a stack of modular elements is associated with one or more supplementary modular printed circuit elements which carry components and which have conductive tracks which terminate at a level corresponding to an alignment level of modular elements of said stack in order to perform the molding, cutting and connection creation steps simultaneously on all the associated modular elements.
3. The method claimed in claim 1 wherein at least one orifice is formed in the same position in the modular elements adapted to constitute a module to form therein a conduit enabling a core to be inserted through said modular elements.
4. An electronic module in the form of a block which includes at least one inductive winding consisting of one or more conductive tracks on a printed circuit film support on which said tracks form turns which are combined to form said coil or parallel and/or coaxial coils, which module includes a stack of modular printed circuit film elements aligned at one edge at least and each carrying one or more turns which are to form part of a winding or of a plurality of parallel and/or coaxial windings and whose tracks terminate on a particular face at aligned edges of stacked modular elements at which conductive tracks are formed to connect turns to each other.

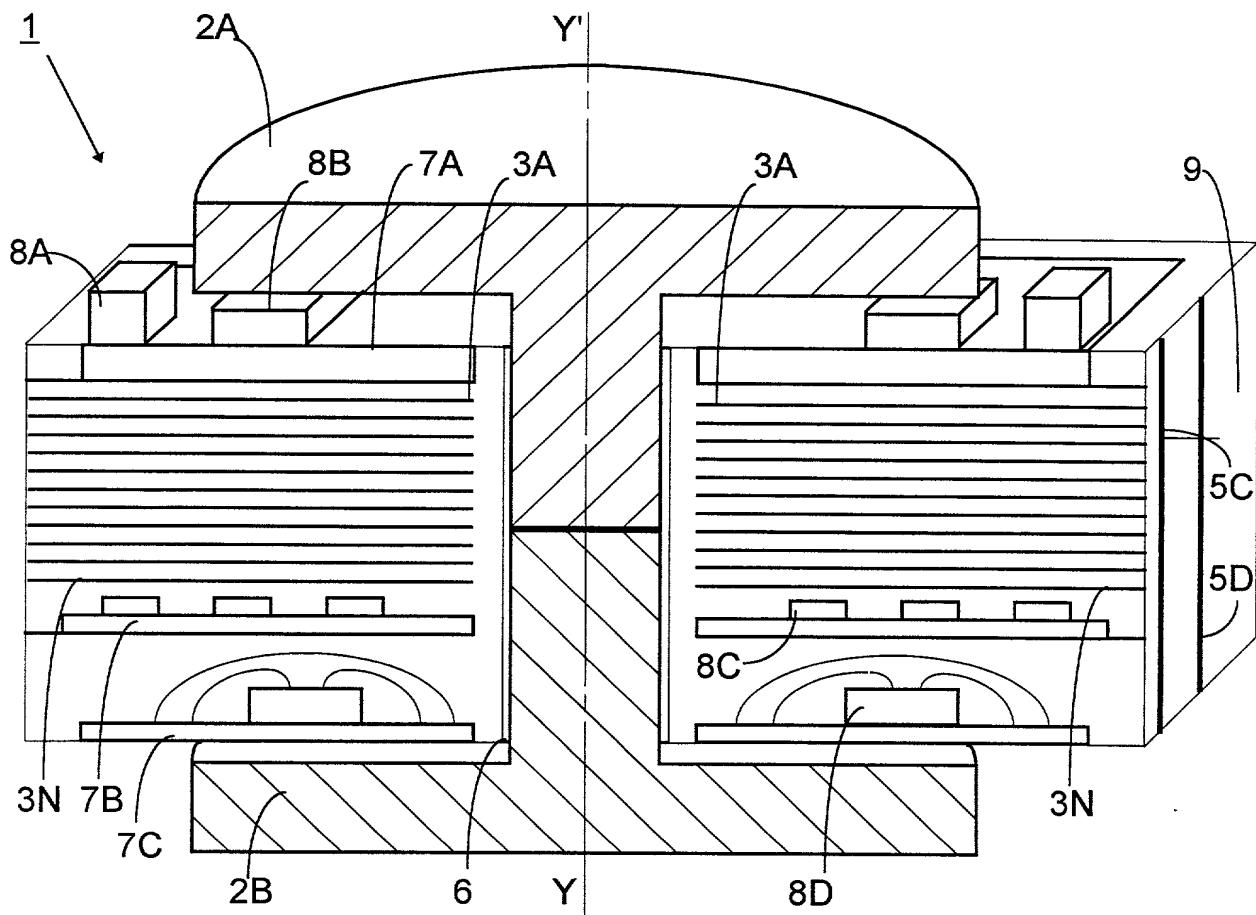

5. An electronic module incorporating a core and taking the form of a block which includes at least one winding made up of conductive tracks on a printed circuit film support adapted to form turns, in a particular arrangement, and wherein at least some turns are combined to form a winding, which module includes a stack of modular printed circuit film elements aligned at one edge at least and each carrying one or more turns which are to form part of a winding or a plurality of parallel and/or coaxial windings and whose tracks terminate at a face defined by aligned edges of stacked modular elements on which are formed conductive connecting tracks for connecting the turns to each other and to connection elements of external connection means, and at least some of the adjacent modules in said stack include identical openings at the center of at least one turn relating to a particular winding to form a passage for a core housed in a conduit formed by successive modules incorporating such openings.
6. The module claimed in claim 4, for example a converter module, wherein at least one supplementary modular printed circuit element carrying components is embedded in the molded block at one end at least of the stack of elements forming a winding or windings and each supplementary element includes conductive tracks terminating at and electrically connected to conductive tracks formed on a particular face of said block by aligned edges of stacked modular elements.
7. The module claimed in claim 5, for example a converter module, wherein at least one supplementary modular printed circuit element carrying components is embedded in the molded block at one end at least of the stack of elements forming a winding or windings and each supplementary element includes conductive tracks terminating at and electrically connected to conductive tracks formed on a particular face of said block by aligned edges of stacked modular elements.

ABSTRACT OF THE DISCLOSURE

A method of obtaining a module including at least one inductive winding made up of one or more conductive tracks on a printed circuit film support on which the tracks form turns which are combined to form a winding or a plurality of parallel and/or coaxial windings includes the following steps:

- 5 - stacking a plurality of aligned modular printed circuit film elements carrying a set of turns which are intended to form part of a winding or of a plurality of parallel and/or coaxial windings and whose tracks terminate at or near the edge or one edge of the element that includes them,
- 10 - molding an insulative material over the stacked assembly of modular elements to constitute a rigid block,
- 15 - cutting the molded block laterally along the stack to expose the conductive tracks at a common alignment level and so that they are flush with the surface of one face of the block, which cutting step is performed at least once, and
- 20 - creating connections on the face or faces of the block with which the modular conductive track elements are flush to interconnect them selectively and to connect them to connection means external to the module.
